ABSTRACT

Based on the literature about cyanobacteria from the mangrove environments of representing the orders, Chroococcales, Chroococcidiopsidales, Gloeobacterales and Synechococcales, we consulted 42 publications (national and international journals and books published from 1980 to 2020). A total of 141 species were referred, in which 72 taxa of Chroococcales, 66 taxa of Synechococcales, 2 taxa of Chroococcidiopsidales and 1 taxon of Gloeobacterales respectively. The dominant family was Chroococcaceae with 46 species, followed by Merismopediaceae and Oculatellaceae with 23 species each, Microcystaceae with 11 species, Aphanothecaceae with 8 species, Heteroleibleiniaceae with 6 species, Shizotrichaceae and Synechococcaceae with 3 species, Entophysalidaceae, Gomphosphaeriaceae, Stichosiphonaceae, Chroococcidiopsidaceae, Chamaesiphonaceae, Coleofasciculaceae, Oculatellaceae and Trichocoleusaceae with 2 species each, Cyanothrichaceae and Gloeobacteraceae with one species each. Cyanobacterial diversity is underestimated in mangrove ecosystems when compared to the number of recognised species.

Keywords: Cyanobacteria, Taxonomy, Mangrove environment, Biodiversity, Distribution

1. INTRODUCTION

Cyanobacteria are a vast and diverse category of prokaryotes with significant biological relevance. They range from unicellular to colonial filamentous and are important components of photosynthetic assemblages in planktic, benthic, epiphytic and edaphic habitats of the mangrove ecosystem (Rajaneesh et al.,

2020). Nowadays, knowledge on the diversity and distribution of cyanobacteria in mangrove environments is very inconsistent. The order Chroococcales embraces all the unicellular or colonial cyanobacteria which do not form true filaments. The families of Chroococcales are classified based on the type of cell division, the polarity of cells and colonies, the form and structure of a colony, formation of various types of mucilaginous strands, layers and the position of cells in a colony (Komarek and Anagnostidis, 1998). According to this work, the cyanobacteria group contains four orders such as Chroococcales, Chroococcidiopsidales, Gloeobacterales and Synechococcales. The taxonomy and classification of Synechococcales and Synechococcus-like cyanobacteria has been extensively studied by Mai et al., 2018 and Komarek et al., 2020. The members of the order Synechococcales are still problematic since it contains coccoid, bacillloid unicellular and colonial genera to simple filamentous forms. This work aims to create a real list of recent cyanobacterial taxa inhabiting the mangrove environment based on modern taxonomic revisions and update nomenclature to reflect current taxonomic understanding for previously described taxa.

2. MATERIAL AND METHODS

The data of coccoid and non-heterocytous members of the order Synechococcales of cyanobacteria in mangrove habitats has been compiled solely from published works of literature from 1980-2020. We used 42 research papers and books published nationally and internationally to create a catalogue of cyanobacterial species and the articles in which they are cited. In mangrove ecosystems, cyanobacteria can be found in a variety of habitats, including epipsammic/edaphic, epizoic, epiphytic, planktic, benthic, and epilithic forms. Some publications may not explicitly mention the occurrence of cyanobacterial species, such species are included under the category 'mangrove environment'. Different techniques for collecting cyanobacteria were described in the original literature mentioned in this study.

The list of cyanobacterial species is based on the published works of literature. We considered only the published works that mentioned cyanobacteria at the species level. Names of taxa are given with proper author citation. Species are classified according to respective family. The species are classified based on the current classification system proposed by Komarek et al., 2014 and Hauer and Komarek, 2021 and the entity of the taxonomically accepted species are verified by Guiry and Guiry, 2021. When a specific or infraspecific taxon is recorded under a synonym if cited, it is represented under the currently accepted names and marked with an equal symbol (=). Newly discovered species are marked with an asterisk symbol (*).

3. RESULT AND DISCUSSION

The total list of cyanobacteria in mangrove environments comprises 141 species that occupy a variety of habitats, including epipsammic/edaphic, epizoic, epiphytic, planktic, benthic, and epilithic forms. From 42 research articles, books and theses published nationally and internationally from 1980 to 2020, we considered cyanobacteria having species-level identification (Table 1). The result showed that 141 cyanobacterial species belong to the orders, Chroococcales (72 taxa), Chroococcidiopsidales (2 taxa), Gloeobacterales (1 taxon) and Synechococcales (66 taxa). From this documentation analysis, the dominant family was Chroococcaceae with 46 species, followed by Merismopediaceae and Oculatellaceae with 23 species in each, Microcystaceae with 11 species, Aphanothecaceae with 8 species, Heteroleibleiniaceae with 6 species, Shizotrichaceae and Synechococcaceae with 3 species, Entophysalidaceae, Gomphosphaeriaceae, Stichosiphonaceae, Chroococcidiopsidaceae, Chamaesiphonaceae, Coleofasciculaceae, Oculatellaceae and Trichocoleusaceae with 2 species in each, Cyanothrichaceae and Gloeobacteraceae with one species in each (Table 2; Figure 1).

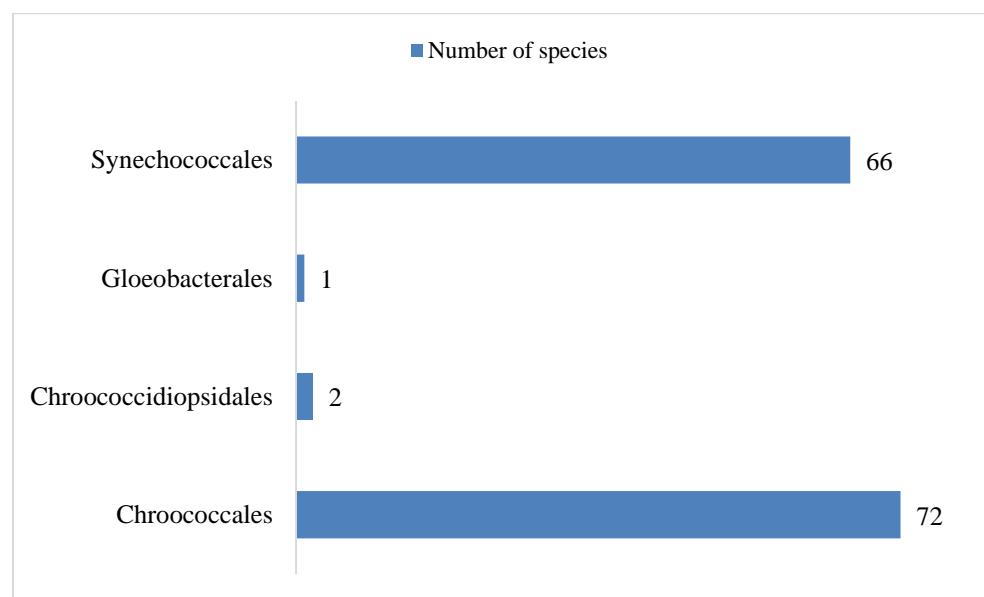

Figure 1: Graphical representation with number of species from the mangrove-associated cyanobacteria according to order.

Studies on the biodiversity of coccoid cyanobacteria from the mangrove environments had started in the 1980s (Potts, 1980; Potts and Whitton, 1980). Research on mangrove-associated cyanobacterial diversity has become increasingly focused since 1990, and there has been a large increase in biodiversity research over the last few decades, although no taxonomic studies have been published in 2020.

The greatest diversity was found in the 'mangrove environment' and epiphytic form (Table 2). Even though planktic cyanobacterial flora has been extensively investigated, it has a low diversity when compared to mangrove ecosystems according to this study. However, the following cyanobacterial species commonly occur as planktic: *Aphanocapsa litoralis*, *Aphanotheca stagnina*, *Chroococcus minor*, *Chroococcus tenax*, *Chroococcus turgidus* and *Gloeocapsa aeruginosa*.

It is very difficult to check the validity while considering the misspelt species name, genus abbreviations in the literature and improper author citations are missing in publications. Therefore, the authors should write the species name and its respective author citation properly.

Several traditional Chroococcales genera were confirmed as non-cyanobacterial organisms, eg. *Cyanotheca* Pascher 1914 (type: Caulobacteria) and *Dactylococcopsis* Hansgirg 1888 (type: Green algae) and they were removed from the revised classification system of cyanobacteria (Komarek and Anagnostidis, 1998). But the genus *Dactylococcopsis* was included under the order Chroococcales (family: Chroococcaceae) with 31 species names in the database (<https://www.algaebase.org/>) at present as well as 22 infraspecific names. Of the species names, 17 have been labelled as taxonomically accepted based on the literature under the species name. Thus, the inclusion of this genus is the subject of controversy.

Some researchers reported the occurrence of *Synechococcus cedrorum* from the mangrove environments and it is currently known as *Cyanobacterium cedrorum*. According to recent taxonomic revision (Guiry and Guiry, 2021; Hauer and Komarek, 2021), the genus *Cyanobacterium* is currently regarded as an invalid genus and suggested for further investigation (Tuji et al., 2021). Thus, the entity of this species name is taxonomically uncertain. Many Cyanobacterial species lack gene sequence information. Despite the current method (Komarek et al., 2014) it depicts phylogeny for cyanobacteria because many morphologically similar taxa are polyphyletic and their taxonomy is a particularly vexing topic.

Acknowledgements

The authors are thankful to the Management, Principal and Head, Research and PG Department of Botany, MES Asmabi College, Kodungallur, Thrissur, Kerala for providing the necessary facilities to carry out the work.

Author Contributions

Arun T Ram: Contributed substantially to the conception and design of the work, literature collection, preparation of the checklist and interpretation of data for the work.

Tessy Paul P: Contributed substantially to the conception and design of the work, literature collection, and revised the manuscript.

Funding:

This research received no external funding.

Conflicts of interest:

The authors declare no conflict of interest.

Data and materials availability

All data associated with this study are present in the paper.
